Models of Teaching connects educators—new and experienced teachers, school and district administrators, school and literacy coaches, providers of professional development, and college educators—to a storehouse of well-developed and studied ways of teaching. These models have strong rationales, use different lines of research, and provide expected student learning examples. All of them are informed by the experience of the hundreds of educators who have used and refined them. Thus, the models represent a base for professional teaching—professional meaning “using research to guide practice.”

Years ago many educators expected that research on teaching would result in a single model that was superior for all types of educational objectives. However, that was not the case when Bruce Joyce began writing Models of Teaching, and it is not the case today. Excellent teaching is made up of a repertoire of models that are very good for particular purposes but need to be assembled to generate a top-drawer learning environment for our students. In other words, teaching is not a one-dimensional operation. Rather, teaching reaches toward different students and across disciplines, responsible for a panoply of standards that require corresponding sets of teaching strategies and ways of reaching students.

Even today some policymakers hope that research will boil down the characteristics of effective teaching into a few principles. Though there are, in fact, some things that we all should do as teachers—and other things we should avoid—the kinds of teaching that will make the most difference to our students and give them the skills for lifelong learning are embodied in teaching strategies or models that provide those skills.

Although the comparison of various professions to medicine is somewhat shopworn, there are important parallels here. In medicine, we don’t have one antibiotic, one regimen, one type of test. Furthermore, some medical specialties are directed toward prevention as well as treatment. Complicating the assessment of both preventive measures and treatment is that interactions are probabilistic. Obesity is bad for the heart, but some thin people have heart trouble. In education we have models that help students learn how to think more clearly, to organize information better, to feel more confident—but like medical treatments, educational treatments are probabilistic. Education is not
like a game of billiards, where a properly struck ball goes where it is supposed to all the time. In our case, it is most of the time.

Over the last 30 years, three important developments have enhanced teaching. One is the continued research on particular models and the development of new ones. Refinements have enhanced their effectiveness. The second is the development of combinations of models into curricula that have great power. Third is the development of electronic technologies that enlarge the library and bring massive amounts of information into the classrooms of even the youngest children. In modern classrooms, hundreds of physical books—fiction and nonfiction—surround the students, and electronic media access to vast resources provides encyclopedias and dictionaries that represent a real advance over print media. The Internet connects modern classrooms to a global network. The study of history is supported by original documents that are easy to access, including graphic material such as the 1,000,000 photos in the Library of Congress collection (www.loc.gov). NASA provides information about space exploration that was available to only a few insiders a dozen years ago. ScienceFriday.com is a delightful site for students and teachers, with simulations available to incorporate into units and courses. Email enables any class to be connected with classes in many of the countries of the world. Young children can follow Jane Goodall’s career from her earliest studies to the development of the worldwide organization of children and adults who work together to create a better environment for all living things (including ourselves).

A note on information and communication technology (ICT) promises and worries: Everybody can profit by reading The Shallows (Carr, 2010) and Smarter Than You Think (Thompson, 2013). Carr lays out the worries that ICT will have seriously negative effects on certain skills and habits. For example, is the use of GPS navigation systems eroding skills in understanding and using maps? Can habitual web-surfing, tweeting, and texting friends generate a goalless, immediate-gratification-oriented state of mind? Or, on balance will the new activities generate new skills and intelligences? This debate will go on for some time.

In our case, we have come from writing manuscript on yellow tablets and typing the result with gallons of corrective fluid on hand. From there, the process evolved to writing and communicating with editors with word processors and graphics files. And at present the print book is also an ebook and is backed up by www.modelsofteaching.org, which brings materials for instructors and students and leads readers to video demonstrations of models, talks providing tips for learning them, PowerPoint tutorials, and more. You don’t just write, today, you relearn how to write.

However, as teachers, we need to teach the models of learning that enable our students to understand and exploit the web and use the communication channels to inform themselves and create global connections where interaction with other societies and their cultures becomes the new normal.
The newly developed science frameworks and literacy standards are greatly improved over their predecessors and provide direction for K–12 teaching and learning. Thus, developed models of teaching can become even more effective because support materials, both print and electronic, have become richer.

Yet the field of education is being fiercely criticized at this time in history. Governmental agencies are pressing schools with unprecedented force because current examinations of student learning, particularly the national studies of educational progress, have indicated serious problems. One such problem is that a third or more of our students are not learning to read and write effectively. How can that be, when teaching strategies and learning resources are developing so well?

A major reason is that those powerful models of teaching are unknown to many educators. They need to be known, learned, and used. This book and the resources connected to it can enable new and experienced teachers to broaden their repertoires, develop rich curricula, and enable all students to succeed. All these models work well with students who come to school with limited backgrounds and knowledge of the English language. Our cause is passionate. Education is not only present life; it is also the life of the future. As time passes, all of these models of teaching will be radically changed or replaced by better ones. For now, let us give the students the best that we know.

What students learn today affects their lives in the long term. When we teach our children to read, we are helping them become lifelong readers. When they are learning to work together, they are becoming collaborative citizens of our democracy. When they learn science, they are developing the inquiry skills and habits to educate themselves and solve current and future problems.

Teaching is helping people create themselves. The effects of a teacher’s work are still maturing a half-century or more after students’ formal education is completed.

New to this edition

This edition is enhanced by productive changes in the written prose, the addition of pictures depicting the teaching/learning process in action, and multimedia dimensions where video demonstrations are integrated with the print book.

Multimedia additions include:

- Integrated demonstrations of models of teaching. The demonstrations were captured in classrooms where expert teachers used the models of
teaching with their students. These can be streamed on demand by both instructors and students.

- The website, www.modelsofteaching.org, which extends additional support to learn the models of teaching with PowerPoint presentations, application guides, and video talks.

Text updates include:

- Newly developed analyses of research and applications of the models. Approximately 30 percent of the prose is new to this edition.
- Applications which demonstrate current policy for school improvement. The models in the book are essential to the implementation of the new Common Core State Standards.
- Updates which shape this book into a core text of Professional Learning and School Improvement Initiatives.
- References to lines of research which constitute the field of education can be found within the text and online at www.modelsofteaching.org. The 9th edition provides an extensive guide for graduate study in education.

Acknowledgments

Bruce and Emily cannot thank these folks enough.

Lisa Mueller has been a wonderful professional partner. She is a fine provider of professional learning opportunities and demonstrations. We have made videos of her marvelous demonstrations, and they are used in many professional learning programs. Her work has provided inspiration for this edition of Models of Teaching.

Brendan Joyce is a great personal companion and has generously given us his technical competence. The site modelsofteaching.org contains manuals, peer-coaching guides, bibliographies, and papers on a number of topics related to this text. The site leads to our storehouse of video demonstrations and links. These and our blog, which enables readers to talk with us, are among Brendan’s contributions.

Lori Kindrachuk, Ralph Kindrachuk, Marilyn and Walter Hrycauk, Ed Witchen, Jim Jutras, and Kim Newlove have been wonderful companions in the organization of our recent Canadian excursions in school enhancement through professional learning.

Grant Dougall, Sharon Champ, and Mary Bishop are enjoyable friends and colleagues and worked with us to develop videos and other materials. For a sample of Mary’s books, take a look at Tunnels of Time (2000).
Maureen Bezanson, Jordan Carlson, Tracy Poirier, and Nicole Simon taught us a lot as they studied several models and the Read to Succeed curriculum. They enriched our understanding as we worked with them to introduce several hundred teachers to those innovations.

From Pearson we have had fine support from editors who were given the responsibility for this edition. Both Linda Bishop and Meredith Fossel took over as editors and worked as if Models of Teaching were one of their new acquisitions. Janet Domingo has managed the production with knowledge, skill, and good-humored determination. She has a dynamic interface with the helpful Katie Watterson of Electronic Publishing Services Inc. Heather Gauen Hutches, the copyeditor, has been a content and stylistic editor as well as setting up the copy for the compositors. She is a real editor in all senses.

Saint Simons Island, GA
Chapter 1 opens our inquiry. We examine the concept of models of teaching and learning and how the models in this book were selected. We begin to study where models have come from—from gifted teacher-innovators is the short answer—and we prepare to acquire these interesting and effective tools. In Chapter 2, we delve into the social aspects of learning, for effective teaching involves the development of communities of learners and equipping students with ways of learning that will enable them to have high quality lives in school and beyond.
CHAPTER ONE

Where Models of Teaching Come From

Constructing Knowledge and Skill to Help Our Students
Construct Knowledge and Skill

Helping new teachers learn to help students learn is more than worthwhile. It’s transporting. The satisfaction when the veil lifts and someone realizes that the only barriers to growth are imaginary and self-imposed is almost unbearable. It’s like watching the birth of a species.

—Fritz Perls to Bruce Joyce

ORGANIZING IDEA

Effective teaching is made up of a toolkit of ways to reach students and help them build their reservoir of knowledge, skills, and enduring values.

SCENARIO

A DAY IN THE LIFE OF SECTION 3A IN SIMONS ELEMENTARY SCHOOL

8:30. Traci Poirier’s third-grade students assemble and find their places in the big horseshoe where their desks are arranged. This week they are organized in groups of three. The members of each group discuss something they have done or thought about since leaving class yesterday. Some share books they have read, films or television programs they have seen, places they have gone, or conversations with their family. All are responsible for sharing some current news event.

8:45. Traci asks whether any students wish to share an item that was shared with them. Nancy shares that Billy had received an email from his pen pal at Taipei Market School in Hong Kong (their recently adopted class, which uses them to
study life in the United States as they study life in Hong Kong). Billy’s pen pal has wondered how many brothers and sisters they have. Everyone writes down his or her number of siblings and passes it to Billy so he can reply. Andy shares that Sharon reported that her sister was getting married on Saturday and wonders whether the class could send her a “best wishes” card. They agree to do so, and Andy volunteers to make a card to send to them.

9:00. The class begins their literacy study. The first inquiry is to get information from a picture of downtown Taipei Market. The class members take turns identifying items in the picture. Traci draws lines from the items to chart paper that surrounds the picture and writes and spells the words, and Andy enters them into the computer. Later they will be printed out on cards for each member of the class. About 30 items are identified and 12 questions generated.

The words are then compared with a set of items they have generated from a picture of the downtown area in their town. To their amazement, about 20 words from each picture are the same. There are more common attributes than different ones. Only six items in the Taipei Market picture are unfamiliar to them. Some of the items are similar, although their representations may be different (a sign in Chinese and English contrasts with a sign only in English). Traci agrees to circle them on the digital picture and email it to the Hong Kong class for identification.

9:30. The class does independent reading. For most students this means reading information from websites that Traci has bookmarked for them and looking through the encyclopedias for information about Hong Kong, taking notes, responding to questions, and developing new questions to explore. Traci tests two students using the Gray Oral Reading Test, looking for fluency and comprehension and searching for clues for her next sessions on comprehension skills for all the students.

10:00. The class works on writing, comparing the two downtown areas using the words they have identified to describe the two pictures. Traci models opening sentences for them, concentrating on how titles and first lines work together to establish topic and theme. She picks up on a prior session where the students classified opening sentences in trade books. Tomorrow they will continue to gather and discuss information as they compare Hong Kong to their own locale, and they will use synectics (see Chapter 7) to explore analogies to structure their writing.

It’s only 10:30, but Traci has already designed activities using cooperative learning strategies, the picture word inductive model, group investigation, and the inductive model, and has planned a follow-up lesson using synectics. As the day progresses, she will begin a unit on plants in their vicinity, using the scientific
inquiry model (Chapter 4), and continue a unit where the properties of number systems are the focus.

Traci has a good-sized repertoire of models of teaching. She knows that success for the students depends on their mastery of the models of learning that are embedded in each model of teaching.

The classic definition of teaching is creating environments to facilitate learning. A model of teaching is a way of building a nurturant and stimulating ecosystem within which the students learn by interacting with its components. Various models pull students into particular types of content (knowledge, values, skills) and increase their competence to grow in the personal, social, and academic domains. We use models in many ways, ranging from planning and using lessons, units, and curricula, to designing instructional materials, including multimedia programs. This concept replaces the “gas station” image of education, where students drop by to be loaded with cognitive fuel. That rather obsolete picture of teaching emphasizes the time-honored picture of a person imparting knowledge or skill by talking, exhorting, and drilling students—taking them through their paces in a grinding fashion. Happily, there are models for designing and delivering good lectures, motivating students, and carrying out effective training. There are times when we need to use the traditional delivery or transmission modes, but when we do, we should use the best models available for designing learning experiences and always be aware of the purposes that any approach can and cannot fulfill.

The last few decades have generated an enormous number of ways to enhance learning environments that existed only in dreams when we were writing the first edition of Models of Teaching. Even then we were using film, video recording and playback, simulations, transparencies, a dozen or so models of teaching, and a variety of other technologies both in our school and our teacher education programs. Those media are still important, but some are still underused in schools and universities. The best models of teaching in the earlier era are still effective today, along with some new ones, and all are enhanced by information and communications technology (ICT) and the available digital education tools.

Our personal and professional heritage

We have been fortunate enough to study with many contemporary educators who have developed and tested a variety of approaches to education and have developed the literature from the 1960s to the present. You will meet some of these shortly. We visit schools and classrooms and study current research on teaching and learning. We also study teaching in settings other
than K–12 schools, such as therapies and training in industrial, military, and athletic settings.

We have found models of teaching in abundance. Some have broad applications, whereas others are designed for specific purposes. They range from simple, direct procedures that yield immediate results to complex strategies that students acquire gradually from patient and skillful instruction.

For *Models of Teaching*, we selected models that constitute a basic repertoire for schooling. With these models we can accomplish most of the common goals of schools—and at a high standard. In any school, students can achieve many goals that only outstanding students in outstanding schools once aspired to achieve. Using models in combination, we can design schools, curricula, units, and lessons. The selection includes many, but not all, of the major philosophical and psychological orientations toward teaching and learning. All have a solid theoretical basis—that is, their creators provide us with a rationale that explains why we expect them to achieve the goals for which they were designed. The selected models also have histories of extensive practice behind them: They have been refined through experience so that they can be used comfortably and efficiently in classrooms and other educational settings. Furthermore, they are adaptable to the learning styles of students and to the requirements of many curriculum areas. Education comes to the new core curriculum standards with a well-stocked storehouse of effective models that address the most demanding standards.

In addition to being validated by experience, all are backed by formal research and disciplined action research that tests their theories and their abilities to yield positive effects. The amount of related research varies from model to model. Some are backed by a few studies; others have hundreds of items of research. As we discuss each model, we provide key references and links—ones that provide access to the research literature and will include page-long descriptions of some of the more revealing studies. They were designed to have positive effects on student learning, and we try to make the warrants (evidence and reasoned analysis) under their stated effects as transparent as possible.

**COMMON CHARACTERISTICS ACROSS ALL MODELS**

Before introducing the models and the families into which we have grouped them, we need to discuss some of the characteristics that all of the selected models share. Learning is the reason for all models, but other attributes are common and integral to the teaching stances represented by the models.

**Helping Students Learn How to Learn**

In their own fashions, each of the selected models includes helping students increase their repertoire of strategies for learning. While using any model, teachers study how the students learn and help them expand their capacity to do so.
• Helping students take responsibility for learning and supporting their efforts. Even when being highly directive, which can be the case while introducing students to new ways of learning, we emphasize that they need to build the capacity to take increasing responsibility for their learning. We move from a need to provide extensive coaching to students to a situation where students are coaching themselves.

• Helping students reach toward new knowledge, skills, and self-understanding. The essence of learning, in school and out, is acquiring new cognitions, abilities, and even emotions and values. A major part of teaching is helping students learn to go beyond where they are. When a six-year-old says, “I don’t like to read!” the underlying emotion is that the child wants to avoid the labor of learning to read and, possibly, the feeling of embarrassment while overcoming difficulties in learning.

A Constructivist Orientation

In their own fashions, all these models seek to help students build knowledge, skills, and values. The instructional aims of several models are almost purely constructivist with respect to academic content (see Vygotsky, 1962). For example, inductive inquiry (Chapter 3) designs the environment so that the student constructs categories, tests them, and from them generates inferences and hypotheses, leading to more testing. A very different model, nondirective teaching (Chapter 14), is designed to help students understand themselves better—to construct self-knowledge—and set goals in the personal, social, and academic domains.

Scaffolding the Learning Process

Built into their processes, all the selected models provide avenues for teachers to “boost” students over difficulties and into the next levels of learning. Vygotsky described the process as seeking the “zone of proximal development” where learning tasks are at a level slightly above the student’s zone of complete comfort, but not so far above that the student cannot manage. Conceptual systems theorists, including the present authors, describe this as providing an “optimal mismatch” designed to enable students to pull themselves into ever-higher levels of capability (see Chapter 20). For example, when teaching new skills with the “training” models (as in Chapter 18), a skill is explained and demonstrated and then the student has to try the skill. At that point, if a student shies away, scaffolding in the form of encouragement may be enough to lift them to try. Possibly more explanation or another demonstration may be in order; but providing motivation may be the difference between success and discouragement. Scaffolding by a teacher on the campus can be a critical support when a student is engaged in distance learning, such as taking part or all of a
course online. More than ever, students need to learn to profit from distance offerings. Even those who are highly skilled at downloading and learning to play games may need help when downloading large quantities of information.

**Formative Assessment and Adjustments**

Closely related to scaffolding is the use of formative assessment to determine whether more or a different kind of support is needed. Sometimes switching to a different model of teaching can help a student find an avenue to learning. ICT is an increasingly important resource for classes as a whole, as well as providing acceleration for students who are sprinting ahead and tutoring for those who need extra help along the way. Helping students become aware of their progress and needs is a critical component of formative assessment. Parents are also brought into the process when they can help, which is frequently.

All models of teaching provide the opportunity for teachers and students to study progress, continue things that are working well, and make adjustments by adding processes and replacing ones that are not working.

**21st-Century Skills**

A strong movement to improve education has emphasized what have been termed *21st-century skills*—types of expertise that have come to the fore as the global, digital world has emerged. Probably “areas of needed knowledge and competence” is a more accurate and useful term than “skill,” but expertise is certainly found in them (see Kay, 2010; Joyce & Calhoun, 2012).

Some 21st-century skills are versions of competence that have been around for a while. Some have been emphasized in the new core state standards, and some are emerging as the digital age ripens. They are not just a collection of computer or ICT skills. Though ICT literacy is important, the vital skills are cognitive: learning to inquire, to build and test ideas, to categorize, to summarize. These have been with us a long time, and they continue to be essential as the opportunities to use them expand. However, everyone needs the skills to use software for word processing, graphics, photo and video editing, searching the web, and locating and using distance instructional offerings. For teachers, mastery of interactive whiteboard technology is increasingly important. Let’s look at some of the other areas that are emphasized by the 21st-century movement.

**Cultural Literacy and Global Awareness**

One of the most striking characteristics of the ICT explosion is the rise of a global, cross-national culture and its effects on relations near and far. These effects change the nature of our society, increase interdependence, and generate a considerable need for intercultural understanding. The implications are apparent as nations and their well-being have become more interdependent,
economies more unified; and we as individuals are in contact with, well, almost everyone. A provincial perspective today can have devastating consequences.

**Collaborative and Cooperative Skills**

We need each other. We always have, but the price of failure to work with others near and far has become unsustainable. Schools need to develop a rich culture to teach students to work and play together. In fact, the campus will be a very important place in the future because it is the major social laboratory for the young. As they reach out into cyberspace and information and ideas zip back from global sites, students need each other for perspective. The simpler cooperative learning models must pervade the school, and the most complex models—cooperative/inquiry models and group investigation—should propel major inquiries. Social media have enormous implications and are affecting life all over the world.

We urge teachers to join the International Association for the Study of Cooperation in Education. We greatly enjoy and learn from their newsletter.

**Creativity**

Convergent thinking enables students to focus on and drive for mastery of knowledge and skills from outside. Divergent thinking plays with information, concepts, pictures, sounds, and objects. Things are moved around, and surprises appear. The process is what the great Bill Gordon called *serious playfulness*, an oxymoron that captures the essence of metaphoric thinking. Ideas that were born on different cognitive planes are placed next to each other, on top of each other, inside each other. Environments populated with analogies lure students into a divergent state. Conception occurs.

The selected models in this book share these characteristics and goals.

## The Families of Models

We have grouped the models of teaching into four families whose members share orientations toward human beings and how they learn. These are:

- The Information-Processing Family
- The Social Family
- The Personal Family
- The Behavioral Systems Family

We turn now to these four families, what they emphasize, and the models and the people who invented them, studied them, and advocated for them. As you read, keep in mind that, as a teacher, you can begin with a few that have wide applicability and then add others to reach particular goals more readily.
The Information-Processing Family

Information-processing models emphasize ways of enhancing the human being’s innate drive to make sense of the world by acquiring and organizing data, sensing problems and generating solutions to them, and developing concepts and language for conveying them. Some models help the learner find information and build concepts and hypotheses to test. Some emphasize teaching concepts directly. Some generate creative thinking. Others teach the processes of the disciplines that underlie the core subjects. All are designed to enhance general intellectual ability.

Eight information-processing models are discussed in Part II and III. Part II is focused on three broadly applicable models and Part III on more narrowly oriented “special purpose” models. Table 1.1 displays their names and the primary developers and redevelopers of each. In some cases, dozens of research-practitioners have contributed to the creation and renewal of particular approaches to teaching.

Inductive Thinking (Chapter Three)

The ability to analyze information and create concepts is generally regarded as the fundamental thinking skill. Although the model has been discussed since ancient times, the contemporary literature was given movement by the work of Hilda Taba (1966) and contemporaries who studied how to teach students to find and organize information and to build and test hypotheses. The model has been used in a wide variety of curriculum areas and with students of all ages—it is not confined to the sciences. Phonetic and structural analysis depend on concept learning, as do rules of grammar. The structure of the field of literature is based on classification. The study of communities, nations, and history requires concept learning. Even if concept learning were not so critical in the development of thought, the organization of information is so fundamental to curriculum areas that inductive thinking would be a very important model for learning and teaching school subjects. The model as presented is based on the recent adaptations by Joyce and Calhoun (1996, 1998), and Joyce, Hrycauk, and Calhoun (2001) in programs designed to accelerate student ability to learn.

This model is listed first because inductive processes are such an important dimension of cognition and cognitive ability, because it inevitably leads to cooperative study and action, and because it combines well with other models.

Scientific Inquiry (Chapter Four)

The National Academy of Sciences has produced a marvelous document that sets forth a forward-looking framework for K–12 science curriculum and teaching. Its comprehensive scope and readable style make it a fine resource for teachers of all grade levels and in all science areas. The inclusion
of material from engineering and technology make applied science more prominent than in the past and their “cross-cutting concepts” that look across the disciplines are an important contribution to curriculum thought. A good place to begin is the website http://nextgenscience.org.

Social sciences also take a similar approach to curriculum and teaching.
The Picture Word Inductive Model (PWIM) (Chapter Five)

Developed by Emily Calhoun (1999), this model was designed from research on how students acquire print literacy, particularly reading and writing, but also how listening–speaking vocabularies are developed. PWIM incorporates the inductive thinking and concept attainment models as students study words, sentences, and paragraphs. The model is the core of some very effective curricula where kindergarten and primary students learned to read and older beginning readers and writers were engaged in “safety net” programs for upper elementary, middle school, and high school students (see Joyce, Calhoun, Jutras, & Newlove, 2006; and Joyce & Calhoun, 2010, 2012). ICT provides access to enormous reservoirs of pictures that can be used in PWIM and support for investigations initiated with the model.

Concept Attainment (Chapter Six)

Originally built around studies conducted by Bruner, Goodnow, and Austin (1967) and adapted and applied to education by Lighthall, Joyce, and others, concept attainment is a close relative of the inductive model. Whereas the inductive process calls on students to form concepts, concept analysis leads the students to attain concepts developed by others. The teacher develops a data set containing exemplars of a concept and items where the attributes of the concept are not present. The students then study pairs of contrasting items until they are clear about the concept. The model is an efficient method for presenting organized information from a wide range of topics to students at every stage of development and also enables students to become more effective at concept formation. A short and succinct demonstration is available online at www.modelsofteaching.org.

Synectics (Chapter Seven)

Developed first for use with “creativity groups” in industrial settings, synectics was adapted by William Gordon (1961) for use in elementary and secondary education. Synectics is designed to help people “break set” in problem-solving and writing activities and to gain new perspectives on topics from a wide range of fields. In the classroom it is introduced to students in a series of sessions until they can apply the procedures individually and in cooperative groups. Although designed as a direct stimulus to creative thought, synectics has the side effect of promoting collaborative work and study skills and a feeling of camaraderie among students. Some recent studies and development by Keyes (2006) and Glynn (1994) have pushed the model a welcome new distance.

Mnemonics (Chapter Eight)

Mnemonics are strategies for memorizing and assimilating information. Teachers can use mnemonics to guide their presentations of material (teaching in such a way that students can easily absorb the information), and they can teach devices that students can use to enhance their individual and
cooperative study of information and concepts. This model also has been tested over many curriculum areas and with students of many ages and characteristics. We include variations developed by Pressley, Levin, and Delaney (1982); Levin and Levin (1990); and popular applications by Lorayne and Lucas (1974) and Lucas (2001). Because memorization is sometimes confused with repetitious, rote learning of obscure or arcane terms and trivial information, people sometimes assume that mnemonics deal only with the lowest level of information. That is by no means true. Mnemonics can be used to help people master interesting concepts, and in addition, they can be a great deal of fun.

**Advance Organizers (Chapter Nine)**

During the last 50 years this model, formulated by David Ausubel (1963), has accumulated a good-sized body of research. The model is designed to provide students with a cognitive structure for comprehending material presented through lectures, readings, and other media. It has been employed with almost every conceivable content and with students of every age. It can be easily combined with other models—for example, when presentations are mixed with inductive activity.

**Inquiry Training (Chapter Ten)**

This model is a direct and fun way to train students to look for causal relationships among variables. See a demonstration with students from India through www.modelsofteaching.org.

**The Social Family**

When we work together, we generate a collective energy called *synergy*. The social models of teaching are constructed to take advantage of this phenomenon by building learning communities. Essentially, classroom management is a matter of developing cooperative relationships in the classroom. The development of positive school cultures is a process of developing integrative and productive ways of interacting and norms that support vigorous learning activity. Table 1.2 identifies the models and several of the developers of the social models.

**Partners in Learning (Chapter Eleven)**

There has been a great deal of development work on cooperative learning, and great progress has been made in developing strategies that help students work effectively together. The contributions of three teams—led respectively by Roger and David Johnson, Robert Slavin, and Shlomo Sharan—have been particularly notable, but the entire cooperative learning community has been active in exchanging information and techniques and in conducting and analyzing research (see, for example, Johnson and Johnson, 2009). The result is a

A large number of effective means of organizing students to work together. These range from teaching students to carry out simple learning tasks in pairs to complex models for organizing classes and even organizing whole schools into learning communities.

Cooperative learning procedures can facilitate learning across all curriculum areas, ages, and academic learning goals, as well as improve self-esteem, social skill, and solidarity.
Group Investigation (Chapter Twelve)

John Dewey (1916) was the major spokesperson for the idea—extended and refined by a great many teachers and shaped into a powerful definition by Herbert Thelen (1960)—that education in a democratic society should teach the democratic process directly. A substantial part of students’ education should be through cooperative inquiry into important social and academic problems. The model also provides a social organization within which many other models can be used when appropriate. Group investigation has been used in all subject areas, with children of all ages, and even as the core social model for entire schools (Chamberlin & Chamberlin, 1943; Joyce, Calhoun, & Hopkins, 1999). The model is designed to lead students to define problems, explore various perspectives on the problems, and study together to master information, ideas, and skills—simultaneously developing their social competence. The teacher or facilitator organizes the group process and disciplines it, helps the students find and organize information, and ensures that there is a vigorous level of activity and discourse. Sharan and his colleagues (1988) and Joyce and Calhoun (1998) have extended the model and combined it with recent findings on the development of inquiring groups.

Role Playing (Chapter Thirteen)

Role playing is included next because it leads students to understand social behavior, their role in social interactions, and ways of solving problems more effectively. Designed by Fannie and George Shaftel (1982) specifically to help students study their social values and reflect on them, role playing also helps students collect and organize information about social issues, develop empathy with others, and attempt to improve their social skills. In addition, the model asks students to “act out” conflicts, learn to take the roles of others, and observe social behavior. With appropriate adaptation, role playing can be used with students of all ages.

The Personal Family

Ultimately, human reality resides in our individual consciousnesses. We develop unique personalities and see the world from perspectives that are the products of our experiences and positions. Common understandings are a product of the negotiation of individuals who must live and work and create families together.

The personal models of learning begin from the perspective of the selfhood of the individual. They attempt to shape education so that we come to understand ourselves better, take responsibility for our education, and learn to reach beyond our current development to become stronger, more sensitive, and more creative in our search for high-quality lives.

The cluster of personal models pays great attention to the individual perspective and seeks to encourage productive independence, so that people...
become increasingly self-aware and responsible for their own destinies. Table 1.3 displays some of these models and their developers.

**Nondirective Teaching (Chapter Fourteen)**

Psychologist and counselor Carl Rogers (1961, 1982) was for three decades the acknowledged spokesperson for models in which the teacher plays the role of counselor. Developed from counseling theory, the model emphasizes a partnership between students and teacher. The teacher endeavors to help the students understand how to play major roles in directing their own educations—for example, by behaving in such a way as to clarify goals and participate in developing avenues for reaching those goals. The teacher provides information about how much progress is being made and helps the students solve problems, but it is the student who has to take initiative—the teacher scaffolds the student’s investigation. The nondirective teacher has to actively build the partnerships required and provide the help needed as the students try to work out their problems.

The model is used in several ways. First, at the most general (and least common) level, it is used as the basic model for the operation of entire educational programs (Neill, 1960). Second, it is used in combination with other

models to ensure that contact is made with the students. In this role, it moderates the educational environment. Third, it is used when students are planning independent and cooperative study projects. Fourth, it is used periodically when counseling students, finding out what they are thinking and feeling, and helping them understand what they are about. Although designed to promote self-understanding and independence, it has fared well as a contributor to a wide range of academic objectives. Cornelius-White’s (2007) review of many years of research on learner-centered teacher–student relationships—119 studies involving more than 300,000 students—examined the impact on cognitive, affective, and behavioral outcomes and reported positive effects and, importantly, that for applications where academic content was included, gains in content were correlated with gains in affect, including self-concepts.

Developing Positive Self-Concepts (Chapter Fifteen)

One of the most difficult tasks in teaching is helping students whose confidence has sunk to a level where they wallow helplessly in failure. They approach the ordinary tasks of the curriculum with dread and avoid those tasks when they can. Here we present a multidimensional approach that attempts to confront grade 4 to 12 students with the very thing they fear—learning to read—and bring those students into the world of success. The influential work of Abraham Maslow has been used to guide programs to build self-esteem and self-actualizing capability for 50 years. We explore the principles that can guide our actions as we work with our students to ensure that their personal image functions as well as possible.

Adaptations to the study of teachers as they expand their repertoire of teaching models have provided a means by which teachers can study their learning styles and processes (Joyce & Showers, 2002). The personal, social, and academic goals of education are compatible with one another. The personal family of teaching models provides the essential part of the teaching repertoire that directly addresses the students’ needs for self-esteem and self-understanding and how to build support and respect among students.

The Behavioral Systems Family

A common theoretical base—most commonly called social learning theory, but also known as behavior modification, behavior therapy, and cybernetics—guides the design of the models in this family. The stance taken is that human beings are self-correcting communication systems that modify behavior in response to information about how successfully tasks are navigated. For example, imagine a human being who is climbing (the task) an unfamiliar staircase in the dark. The first few steps are tentative as the foot reaches for the treads. If the stride is too high, feedback is received as the foot encounters air
and has to descend to make contact with the surface. If a step is too low, feedback results as the foot hits the riser. Gradually, behavior is adjusted in accordance with the feedback until progress up the stairs is relatively comfortable.

Capitalizing on knowledge about how people respond to tasks and feedback, psychologists (see especially Skinner, 1953) have learned how to organize task and feedback structures to make it easy for human beings' self-correcting capability to function. The result includes programs for reducing phobias, learning to read and compute, developing social and athletic skills, replacing anxiety with relaxation, and learning the complexes of intellectual, social, and physical skills necessary to pilot an airplane or a space shuttle. Because these models concentrate on observable behavior and clearly defined tasks and methods for communicating progress to the student, this family of teaching models has a firm research foundation. Behavioral techniques are appropriate for learners of all ages and for an impressive range of educational goals. Table 1.4 displays the models and their developers.

Explicit Instruction (Chapter Sixteen)

Although reading without comprehension is not really reading, the explicit teaching of comprehension strategies has not been common in U.S. schools. However, research and development, practice, and results have given us a serviceable model. Every teacher will find this model useful.

Mastery Learning (Chapter Seventeen)

The most common application of behavioral systems theory for academic goals takes the form of what is called mastery learning (Bloom, 1971). First, material to be learned is divided into units ranging from the simple to the complex. The material is presented to the students, generally working as individuals, through appropriate media (readings, tapes, activities). Piece by piece, the students work their way successively through the units of materials, after each of which they take a test designed to help them find out what they have learned. If they have not mastered any given unit, they can repeat it or an equivalent version until they have mastered the material.

Instructional systems based on this model have been used to provide instruction to students of all ages in areas ranging from the basic skills to highly complex material in the academic disciplines. With appropriate adaptation, they have also been used with gifted and talented students, students with emotional problems, and athletes and astronauts.

Direct Instruction (Chapter Eighteen)

From studies of the differences between more and less effective teachers and from social learning theory, a paradigm for instructing directly has been assembled. Direct statements of objectives, sets of activities clearly related to the objectives, careful monitoring of progress, feedback about achievement, and tactics for achieving more effectively are linked with sets of guidelines for
facilitating learning. Two approaches to training have been developed from the cybernetic group of behavior theorists. One is a theory-to-practice model and the other is simulation. The former mixes information about a skill with demonstrations, practice, feedback, and coaching until the skill is mastered. For example, if an arithmetic skill is the objective, it is explained and demonstrated,
practice is given with corrective feedback, and the student is asked to apply it with coaching from peers or the instructor. This variation is commonly used for athletic training.

Simulations are constructed from descriptions of real-life situations. A less-than-real-life environment is created for the instructional situation. Sometimes the renditions are elaborate (for example, flight and spaceflight simulators or simulations of international relations). The student engages in activity to achieve the goal of the simulation (to get the aircraft off the ground, perhaps, or to redevelop an urban area) and has to deal with realistic factors until the goal is mastered.

| In sum |

The models briefly introduced here have been selected from many other possibilities. We are sure these can be used in classrooms and in cyberspace; their effectiveness has been substantiated by experience and formal research. As we will see later, achieving mastery over them takes practice. Teams of teachers working together to master a model can share reflections and companionship as one progresses from being a novice to achieving executive control over that model.
Building the Community of Expert Learners

Taking Advantage of Our Students’ Capacity to Learn (and Ours)

A school teaches in three ways: by what it teaches, by how it teaches, and by the kind of place it is.

—Lawrence Downey (1967)

In a perfect world, we would come to adulthood knowing we had full-blown wisdom about how to raise children and how to teach them from infancy to adulthood. At least we’d be aware that those knowledges and attendant skills were latent, lying just below the surface and ready to come to life when we had babies or accepted jobs as teachers. In our imperfect world, we are not so lucky; most of us have to learn a lot about how to parent and how to teach. But we are not without equipment, because what we need does lie within us if we will allow it to find its way into our consciousness. Models of teaching and learning are designed to make that awakening a stimulating and positive adventure. Information and communication technologies (ICT) are going to help, particularly by bringing information and ideas closer to us and our children and learners all over the globe.

What People Bring to Life: Natural Learning Capability, Curiosity, and Creativity

From birth, we are programmed to reach out to living and nonliving things. Think how we loved our pillow, our blanket, or some stuffed toy. We not only loved them, we imbued them with a love that they returned to us. In the most desolate circumstances, a baby will treasure a stick or a stone if that’s all there is at hand. Those of us who have pets learn how much they are an opportunity to extend our capacity for love and companionship. The other day Bruce
interrupted a telephone conversation to say something to our cat. The woman on the other end said, “Don’t worry. I talk to my dog all the time.”

Knowing how to love and care for things beyond ourselves is a great tool with which to begin our lives. We know that we and other creatures need affection and attention, and we know something about how to provide these to others even as we work our way through the egocentricity we were also born with. But we were not born with meanness or cruelty. Those have to be learned in a perverse environment.

People are also natural scientists. We investigate routinely at birth, looking at and touching things and manipulating them to see what happens. We just can’t help it, for we want to know how our world works. We are a handful at that point, and those who care for us have to scoop us up at times just before we are about to connect ourselves to the electrical system or the oven. But we continue studying our world, crawling around and poking things to find out what happens.

Children don’t just collect information; they also organize it. We’re inborn scholars in the sense that we naturally build concepts and generalizations. We’re born with an innate ability to discriminate things and organize all sorts of stuff into categories. As infants, we sorted things as hard or soft, comfortable or uncomfortable, rough or smooth, noisy or quiet. We learned to tell Mom from Dad, the cat from either, the cat from furry toys. We learned words. There’s a big one—as we listened to the world around us, we sorted words, rapidly gaining control and making choices as we shouted Da to access Dad, Baa for our bottle, and Ju for our juice. We want to learn language—to listen and speak fluently. Deaf children are exultant when they discover that sign language exists. And there is no more thrilling moment to watch than when an improvement in hearing aids lets the world of sound into their minds and hearts.

Early language acquisition is easy because we’re natural linguists. Once we have about 50 words we begin to make sentences, at first just two or three words long. As our minds seek to make sense of our world, we figure out which words are used for what. Wherever we find ourselves, we listen and learn to speak. In Greece, we learn Greek; in Thailand, we learn Thai; in Argentina, we learn Spanish. In Switzerland, we may learn French, German, and Italian, all at once. By the time we’re 4 or so, we know the structure of our language and can understand and speak several thousand words—a basic storehouse that we will hear and process all our lives.

Scholars who study language development are continually amazed as they study young children’s language development. Infants progress rapidly from when they utter a first word; by age 2, the average speaking vocabulary is 500 to 600 words. By age 5, the speaking vocabulary averages about 5000 words. By then children are also using the basic structures of language (such as syntax), and phonemic and phonological awareness is established for many.
There is considerable variance—a range of 2500 to 7500 words is common in populations that have been studied (Biemiller, 2010).

We are beginning to understand more about why homes and preschools have large effects. A major factor appears to be the amount of talk in the home and the nursery and preschool (Barnett, 2001; Dickinson, McCabe, & Essex, 2006; Hart & Risley, 1995). If the environment is language dense and rich, the natural linguist takes over and the child learns more words and more about the structure of the language in his or her environment. By surrounding the students with language, expertly taught preschools and kindergartens can level the field considerably. But, by age 5, children from the most linguistically poor families can learn to read if the appropriate models of teaching are used. The early years (K–2) curricula need to increase listening and speaking as well as reading and writing vocabulary. Overall vocabulary measured in grade 2 predicts 30 percent of the variance in reading comprehension in grade 11 (see Cunningham, 2009; Graves, 2006).

Just as learning language is a natural capacity, people are born anthropologists. We learn the norms of our culture rapidly by watching the people around us and imitating them. We’ll eat literally anything, if our people do, and we’ll stay away from any food our social environment shuns. Most of us mimic, then follow, the customs of our immediate world. If the people around us shake hands on greeting, we shake hands; if they hug, we hug; if they bow, we bow. In China, we’ll learn Chinese customs. In England, we’ll soon look and talk like miniature English people.

What can we—the parent, relative, neighbor, the teacher candidate, the formal educator, the experienced schoolteacher—do to strengthen, nurture, and channel these wondrous human capabilities? What is our role? Our work? The first principle is learning to work with nature and avoid working against it. If we learn to build classroom and school environments that capitalize on the way we are—the way people are—the natural learning ability of children will make us great teachers and parents. One of the inherent premises of inductive and other effective models of teaching is that we do not have to feed our knowledge of language, science, social studies, and mathematics to our students. Rather, we help them enhance their ability to learn. If we build learning communities that draw the students into inquiry into subject matter and help those students engage with it conceptually, they will master any subject. And, they will be learning more than our specified curriculum objectives: they will learn how to learn ever more powerfully, because they are practicing their thinking, because they have more information, because they are using this information, and because learning and understanding are satisfying. (See the introduction to the new science and English language arts standards for an elaborate affirmation of this position: National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010; National Research Council, 2012.)
Let’s turn to the process of building those learning communities—the nur- turant and stimulating environments that enable the capacities of our students to flourish as they educate themselves.

**Creating Communities of Expert Learners**

*This book could have been called Models of Learning.*

—Emily Calhoun to Bruce Joyce, maybe a hundred times

Let’s begin by visiting two first-grade and two tenth-grade classrooms at 9:00 on the first day of school. All of the teachers are using teaching/learning models. The first part of each scenario describes the teaching/learning processes on the campus; that is, they each take place in a classroom in a school. Then we add connections to resources on the web and ways of obtaining and managing information, and they each become a *hybrid*—the campus and the web are working together.

**Scenario**

**The First Hour of School in Grade 1**

The first-grade children are gathered around a table on which a candle and jar have been placed. The teacher, Jackie Wiseman, lights the candle and, after it has burned brightly for a minute or two, carefully covers it with the jar. The candle grows dim, flickers, and goes out. Then she produces another candle and a larger jar, and the exercise is repeated. The candle goes out, but more slowly. Jackie produces two more candles and jars of different sizes and repeats the process. Again the flames slowly go out.

“Now we’re going to develop some ideas about what has just happened,” she says. “I want you to ask me questions about those candles and jars and what you just observed.” The students begin. She gently helps them rephrase their questions or plan experiments. When one asks, “Would the candles burn longer with an even bigger jar?” Jackie responds, “How might we find out?” Periodically, she will ask them to dictate to her what they know and questions they have and writes what they say on newsprint paper. Their own words will be the content of their first study of reading.

Jackie tells the children that she has planned another demonstration to provide them with more information. Using the interactive whiteboard as the monitor, she takes them to a website called The Naked Scientists (www.thenakedscientists.com) and, within that site, to the Kitchen Science page and then to an item called Losing Air.
She reads students the instructions about the demonstration, beginning with needed materials, which she shows and discusses as she readies the experiment.

The materials are

- A transparent Pyrex dish
- A candle designed to float
- A quart-sized wide-mouthed jar without a top
- Three coasters heavy enough to sink in water

Then Jackie pours water into the dish to a level of about 1½ inches, puts the coasters on the bottom of the dish, places the candle on the water, and lights it. After ensuring that it is burning well, she lowers the jar over it until it is resting on the edges of the coasters. In Figure 2.1 you can see the arrangement as if you were looking at it with your eyes level with the top of the dish.

What happens? First, air bubbles escape from the jar, rising through the water. Then, the candle goes out and the water rises in the jar.

Jackie asks the students to describe the materials, their arrangement, and what happened after the candle was lit. She writes their answers on the whiteboard and takes care that the materials are identified and the events are described in order. They read the descriptions in unison after Jackie reads each one.

Then, she asks them to try to provide explanations of what happened: the onset of the bubbles and then the water rising in the jar.

Jackie is beginning her year with the model of teaching we call inquiry training (see Chapter 10) and is transitioning to the model we refer to as scientific inquiry.

**FIGURE 2.1** Demonstration using candles on water

![Diagram of demonstration using candles on water](image-url)
The model begins by having the students encounter what will be, to them, a puzzling situation. Then, by asking questions and conducting other investigations, such as trying larger and smaller jars, they build ideas and test them.

The inquiry leads them to the school library, where the librarian, Cathy Rodelheimer, shows them *Being a Scientist*, by Natalie Lunis and Nancy White. *Being a Scientist* is a big book (approximately 14 × 20 inches), heavily illustrated with photographs, that Jackie can read to students. When she reads the book, she asks her students to describe what they see in the lavish photographs that accompany the text. She also notes on the interactive whiteboard some words they would like to learn to read, including “you,” “yes,” and “scientist.” She spells them as she prints them on the board and asks the children to spell them by repeating after her.

After each page, she also asks the students to dictate a summary or provide an answer to a question posed in the text. She writes these on the board, reading aloud what she writes. For example, one picture discusses the concept of measuring. On the next page, the photo shows a girl mixing ingredients for a cake and using a beaker to measure flour. The text asks how the young woman can find out how much flour she needs (Lunis & White, 1999).

The inquiry leads to what we call the great new global library—the information and ideas indexed on the web. The computer that is connected to the whiteboard contains Encarta (Jackie has an old copy on CD) and Compton and Britannica encyclopedias (see http://kids.britannica.com) that, with her help, the students can consult as the inquiry proceeds. Most important, in this and other projects, Jackie is building a community where the students will work together as they learn to read and write and explore social studies, science, and mathematics.

How does the candle project fit with the spirit of the new core curriculum standards? The science standards suggest that students learn content in such a way that they experience and learn how knowledge is generated. The science core is also unified by continuous hands-on experience. All students, K–12, should conduct investigations in the sciences and participate in projects where the methods and concepts of the sciences are employed. The experiential learning provides the concrete ground for understanding more complex and abstract principles as they are encountered, as well as the application to aspects of life that are within reach. The investigative frame of reference is a lifelong outcome. The Common Core State Standards for English Language Arts & Literacy stress literacy in the sciences—note how Jackie mixes gathering information from books, the web, and hands-on experiences and how this is based on the evidence presented in Chapter 1.

The social studies are similar—learning how to build knowledge and ideas while studying the immediate social environment. (See *Social Education* and *Social Education for the Young Learner*, publications of the National Council for the Social Studies).
In Jackie’s classroom, ICT will be present in several ways throughout the school day. An author from Tumblebooks (www.tumblebooks.com/library) will read one of her books to the children, and a clip from “Life in Space” will introduce the international space station (www.discoveryeducation.com).

**Scenario**

**INVESTIGATION INTO ELECTROMAGNETS BEGINS THE YEAR NEXT DOOR**

Next door, the children are seated in pairs. In front of each pair is a pile of small objects, as well as a large nail, wires, and a battery. Their teacher, Jan Fisher, explains that they are going to study magnetism: “The first thing I want each pair to do is to put your nail next to each of the things I have set in front of you. Then, let’s discuss what we learn.”

The students take turns exploring the objects with the nail. Each pair reports that nothing happens as the nail passes near or touches the objects. A dozen of those objects are medium-size paper clips. Jan records their statements on the whiteboard.

Then she shows them how to wrap the insulated wire around the nails and attach the uninsulated ends to the batteries through a switch. They connect the ends and turn on the switches. “Now, find out what happens when you bring it close to or touch the things in front of you. Sort the objects according to what happens.” The students soon have two piles of objects in front of them: one with items that have been pulled to the nail and one with items that have not. All the paper clips stuck to the nail. One student reports that his nail will hold a string of paper clips. The other students confirm it. The consensus is that the nail will hold a string of about six. Jan records their statements and they read them with her. Like Jackie, Jan also brings up an experiment from The Naked Scientists’ collection at www.thenakedscientists.com; hers is “Make Your Own Electromagnet.” She explains that the collection shows how to explore various science topics with common materials and also provides explanations and avenues for further inquiry.

Jan has begun with the model we call *inductive thinking* (Chapter 3). That model begins by presenting the students with a data set or having them build one, then helping them study the items in the set and classify those items. As they develop categories—in this case noting how the objects respond to a magnetic field—they will build hypotheses to test. Jan will study how the students think and what they see and don’t see to help them learn to attack this and other content areas as a community of inductive thinkers.
Like Jackie, Jan reads *Being a Scientist* to students, and they discuss the content of the text and pictures. That is followed by *Discovering Electricity* by Natalie Lunis, which includes a section on the electromagnet and how it is used. Finally, they make a brief trip to the Internet, where Jackie leads them through the first paragraph of a text that describes the development of the electromagnet some 200 years ago (http://physics.kenyon.edu/EarlyApparatus/Electricity/Electromagnet/Electromagnet.html).

Both teachers have begun to build learning communities and introduce their students to models for learning. Their actions make clear that these communities will be inquiring ones. By writing down the students’ statements and questions and reading them with the students, these teachers signal that reading and writing will be emphasized from the beginning.

Each teacher will save the statements and select a number of words that will be printed out so that each student can have a copy of that list with each word on a separate card. Later, we will look in on these classes again and see what is done with the word cards.

Like Jackie’s class, Jan’s students will be introduced to Tumblebooks (www.tumblebooks.com) and, as the inquiry proceeds, fresh topics will be brought to virtual life through Discovery Education (www.discoveryeducation.com).

### Scenario

**OPENING A HIGH SCHOOL CLASS WITH A CONTEMPORARY SOCIAL ISSUE**

About a mile away from the elementary school where Jackie and Jan teach, Marilyn Hrycauk’s tenth-grade social studies class begins with a videotape taken in a California courtroom, where litigation is being conducted over whether a mother can prevent a father and their 12-year-old son from having time together. The parents are divorced and have joint custody of their son, who lives with the mother.

The tape presents the opening arguments in the case. Marilyn asks the students to individually generate the issues as they see them and to request further information about the situation. She then urges them to share their ideas and asks each student to list the shared ideas under the headings of “issues” and “questions.” They find it necessary to develop another category called “positions and values” for some of these shared ideas.

The inquiry will continue by watching more segments of the tape and analyzing several abstracts of similar cases that Marilyn has collected for them. One such case is their first homework assignment. Gradually, through the week, Marilyn will lead the students to develop sets of policy statements and the values that underlie...
the various possible policies. As the exercise proceeds, she will be studying how well the students are able to clarify facts, distinguish value positions, and discuss differences between seemingly opposing values and policy positions. She, too, is beginning the development of a learning inquiry and is herself an inquirer into her students and their learning. Inevitably the inquiry will reach to the web, consulting sources like www.courts.ca.gov/selfhelp-custody.htm. They will also examine books like *The Custody Book* by Judge James W. Stewart and *Child Custody* by James C. Black and Donald Cantor.

Marilyn has opened her class with the *jurisprudential model of teaching*, which is designed to lead students to the study of public policy issues and their own values.

---

**SCENARIO**

**ANOTHER SET OF SOCIAL ISSUES FOR OUR TENTH-GRADE CLASS**

Marilyn’s class then moves to Shirley Mills’s English course, which opens with a scene from the film *The Milagro Beanfield War*. The students share their reactions to the setting, action, and characters. When they want to defend their interpretations or argue against the ideas of others, Shirley announces that, for the time being, she wants to preserve their differences so that they can inquire into them. She then passes out copies of the novel of the same name by the author John Nichols and asks them to begin reading it.

During the week, she will encourage them to explore the social issues presented by the book and film and compare the devices used by the author and filmmakers. She will watch closely what issues and devices students see and don’t see as she works with them to build an inquiring community. The search leads the students into investigations into life in the Southwest, beginning with demographic information and from there to websites developed by cities and towns in New Mexico. They begin with www.50states.com/newmexic.htm. They are surprised to find that the average elevation of New Mexico is 5700 feet above sea level, that about a third of the 2,000,000 people have Spanish as their first language, and that the Navajo and Pueblo populations add up to about 300,000.

Shirley has introduced her students to the *group investigation model* (see Chapter 12), a powerful cooperative learning model she has used to design her course. The model begins by having students confront information that will lead to an area of inquiry. They then inquire into their own perceptual worlds, noting similarities and differences in perception as the inquiries proceed.
UNDERSTANDING OUR STUDENTS AND BUILDING COMMUNITIES

Education continuously builds ideas and emotions. The flux of human consciousness gives the process of education its distinctive character and makes teaching and learning such a wondrous, ever-changing process. The children come to school filled with experiences in their heads and hearts and in patterns of behavior that will be built on as they mature. Models of teaching are the product of the teachers who have beaten a path for us and hacked out some clearings where we can start our own inquiries. All teachers create a repertoire of practices as they interact with their students and shape environments intended to educate them. Some of these practices become the objects of formal study—they are researched and polished and become models we can use to develop the professional skills that we bring to the tasks of teaching.

A SCHOOL WHERE EVERYBODY CAN LEARN

Imagine a school where the various models of teaching are not only intended to accomplish a range of curriculum goals (learning to read; compute; understand mathematical systems; comprehend literature, science, and the social world; and engage in the performing arts and athletics) but are also designed to help the students increase their power as learners. As students master information and skills, the result of each learning experience is not only the content they learn, but the increased ability they acquire to approach future learning tasks and to create programs of study for themselves.

In our school the students acquire a range of learning strategies because their teachers use the models of teaching that require them. Our students learn models for memorizing information. They learn how to attain concepts and how to invent them. They practice building hypotheses and theories and using the tools of science to test them. They learn how to extract information and ideas from lectures and presentations, how to study social issues, and how to analyze their own social values.

Our students also know how to profit from training and how to train themselves in athletic, performing arts, mathematical, and social skills. They know how to make their writing and problem solving more lucid and creative. Perhaps most importantly, they know how to take initiative in planning personal study, and they know how to work with others to initiate and carry out cooperative programs of inquiry. These students are both challenging and exhilarating to teach because their expanded learning styles enable us to teach them in the variety of ways that are appropriate for the many goals of education.

When we visited the previous four teaching/learning scenarios, we saw those teachers and students beginning to develop the learning communities
they would work in throughout the year. Schools and classes are communities of students, brought together to explore the world and learn how to navigate it productively. We have high hopes for these learning communities. We hope their members will become highly literate, that they will read voraciously and write with skill and delicacy. We hope they will understand their social world, be devoted to its improvement, and develop the dignity, self-esteem, and sense of efficacy to generate personal lives of high quality.

These aspirations are central to the study of teaching and guide the research that has resulted in the rich array of teaching models that give learning tools to our students and stimulate our inquiry. Can we design such schools and classrooms? You bet we can! Can we do it by using the developed teaching strategies as formulas? No, we can’t! Do we have to study the kids’ responses and continuously adapt the ways we teach? You bet we do! So, let’s continue our inquiry. As we prepare to do so, let’s again visit some teachers who are beginning to organize their learning communities.

**Scenario**

**READ! JUST READ! A TONE IS SET**

The first few minutes with a class set a tone.

Evelyn Burnham’s fifth-grade class enters the classroom on the first day of school. They find all the computers on. On each screen is the same message: “Please check a book out of the classroom library. Select a desk, which will be yours for the time being, and begin reading the book silently. If you come across a word you can’t figure out, write it on a card in your Words to Learn box or look it up in the Talking Dictionary.”

The kids are a bit confused, but, looking around the room, they find the bookshelves that are labeled “Classroom Library.” They find cards on one of the shelves and sign out their books, locate their desks, and begin to read. Evelyn moves about the room, introducing herself to the students and making name tags for them.

**Scenario**

**INVESTIGATING WORDS ON DAY ONE**

Bonnie Brigman’s second-grade class enters the classroom on the first day of school. They find that their desks have been labeled with their names, and a note on the board asks them to find their desk and begin reading a set of sentences that are on the desks. Bonnie also asks them to write down any words they have trouble pronouncing or understanding.
Like Evelyn, Bonnie moves about the room, introducing herself to the children. She invites parents to stay and asks them to read a description of the Just Read program that she has printed for them.

After about 15 minutes, Bonnie asks the kids to share any words they had difficulty reading. When a child indicates a word, Bonnie asks how many others had difficulty reading the same word. She has her clipboard on her knee with a list of the students’ names, and she records the words they have trouble with. The sentences are constructed to include words representing most phonetic combinations, and in each sentence there is a word that she is fairly sure will be new reading vocabulary to them, so that they have to use context clues to comprehend the word.

BEGINNING WITH GANDHI

Bruce Hall’s eighth-grade social studies class enters the room on the first day of school. The students find name tags on the desks and locate their seats. He gives them a minute to get settled, introduces himself, and flips on the DVD player. A scene from the film Gandhi appears, and the students watch while Gandhi delivers the famous speech on passive resistance. When the scene is over, Bruce asks the students to write their impressions. “I want us to get started on our study of the world. I also want to get a look at how you write.”

“Is this an English class?” asks one of the students.

“Well, it’s called social studies, but all classes include literacy. We’ll write a lot this year.”

GENERAL PRINCIPLES

All three teachers, working with students of different ages, do some similar things. All three let their students know, by the tasks they give them, that they are in a learning environment. They provide instructions and get things moving right away. They do not spend time telling the children how to behave; they assume that their instructions will be followed. And they are right—the kids get right to work. In addition to taking those students into the learning process without delay, they are kind and affirmative. All three teachers are studying their students from the moment they enter the classroom. They are preparing to modulate as they gather information on what the kids can do and how they do it.

All three assume that the students can manage their own activities, checking out books, reading independently, and writing on demand. All three expect independent reading and writing; they begin their Just Read programs (see Joyce, Calhoun, & Hrycauk, 2003) the first day of school. The students record
books read each week and set their goals for amount and types of texts they will read. The class tallies the number of books read and sets goals and plans celebrations for when those goals are reached. The program generally quadruples amounts of reading by students with significant effects on the comprehension scores in standardized norm-referenced tests.

All three teachers radiate confidence in themselves and in their students. They let the kids know that they are the adults in the teaching/learning transaction, but do not pretend they are all-knowing gods or goddesses. If the students get stuck, they say, “Well, let’s try something else and see if it works.” These teachers let the kids see themselves as learners.

**FORMATIVE ASSESSMENT**

Closely related to scaffolding is the continued use of formative assessment of learning to determine whether more or a different kind of support is needed. Essentially, the teacher watches learning closely and provides support—from simple encouragement to special assignments and possibly tutorial sessions. Sometimes switching to a different model of teaching can help a student find an avenue to learning. We will provide examples as we present each model, but a brief example here may help explain how it works.

**SCENARIO**

**DATA AND DECISIONS**

Let’s imagine that a fifth-grade teacher (Traci Poirier, from Chapter 1) is studying aspects of her students’ knowledge of arithmetic as she plans the year’s work. She gives the class a test that includes some examples of multiplication and division. There is quite a difference in the pace with which the students calculate the products and quotients, although the test is not timed and she gives no indication that speed is valued. Further, the slower students made more errors when calculating. She decides to give them a test on knowledge of the multiplication facts and does so by presenting examples on the whiteboard and asking the kids to write down the products privately at their desks. Traci collects their papers and scores them. Ten of her 25 students answer all the examples correctly, eight answer from 60 to 70 correctly, and seven range from 40 to 59, with the majority of their misses in the 6 to 9 times tables.

She decides that for the next two weeks the students will be organized into three groups based on these scores. The group who answered all the examples correctly (she calls them the “ten” group) will engage in inquiries designed to advance their knowledge and test their limits. To begin with, she asks them to explain the “property of 9” phenomenon where the product of 9 and any other number can be divided by 9 with no remainder. They are to develop explanations and present them to the class. In addition, they will be connected to the Everyday
Math group at the University of Chicago and the unit on “Multiplication and Division Numbers Stories” where they can study applying the facts to real-life problems (http://everydaymath.uchicago.edu/parents/4th-grade/em-at-home/unit_5).

The “almost” group is divided into pairs whose task is to help each other master all the facts in any way they choose. However, Traci also leads them to the PBS online package called “A Place for Numbers,” which provides a nice review and application to estimation—a very important topic (www.pbslearningmedia.org).

The “worker bees” are also organized into pairs to study the facts they need to learn and they (and their parents) are connected to the PBS site.

Traci takes all the students through exercises with the multiplication facts matrix, having them discover regularities in the products (as in the “threes” table, where products follow a “3, 6, 9” pattern).

After a week she retests their knowledge of the facts and adds problems requiring estimation for the “tens” group. The “almosts” are now “tens” and she adds the everyday number stories unit to their diet. Based on the results, she will continue asking the students to study the multiplication facts and add emphasis on relations to the characteristics of the number system. The class goal is to have all students with mastery of 95 percent or more. For worker bees who have gained just a few facts, she sets up 10-minute peer-tutoring sessions where “tens” students work with the bees on a few facts each day. Her email to the parents of the bees includes a list of the facts each one needs to master and a link to the Everyday Math site (http://everydaymath.uchicago.edu).

The scaffolding orientation involves keeping track of student progress and adjusting instruction to ensure mastery of important basic information and skill. It is important that students are aware of their progress and needs and that parents are brought into the process when they can help.

**In sum**

All models of teaching provide the opportunity for teachers and students to study progress, keep doing things that are working well, and adjust by adding processes and replacing ones that are not working. To teach well is to embrace this adventure—learning how the students’ knowledge, cognitions, and emotions interact with environments and how both change in the process. To teach well means to be caught up in an inquiry that has no end: we are never finished with this adventure, never satisfied with the arts and sciences of making those inferences, never done with the construction of models of learning and teaching that are built on the guesses we make about what is going on in all those minds. What Ernest Hemingway said about writing we can say about teaching: “We are all apprentices in a craft where no one ever becomes a master.”
